VISUALLY LOSSLESS CONTENT AND MOTION ADAPTIVE SHADING IN GAMES

ACM I3D, May 21-23 2019 - Montréal, Canada

OUTLINE

Background

Content adaptive shading

Theory & Results

Motion adaptive shading

Theory & Results

Demo: Wolfenstein II: the New Colossus

The background is a dark, textured surface with a network of thin, glowing green lines. These lines connect various points, some of which are highlighted as bright green dots. The overall effect is a complex, interconnected web of light against a dark backdrop.

BACKGROUND

OVERVIEW

Why do we need adaptive shading?

The cost of pixel shading increases dramatically in today's games

- Enhanced realism and special effects
- Higher resolution and framerate

OVERVIEW

Pixel Shading Inefficiencies

Shader gets run
every single pixel,
regardless of content

MAIN CONTRIBUTIONS

Questions we answered in this paper

1. What is the error caused by lowering shading rate?
2. How is visual error affected by motion?
3. How to implement adaptive shading efficiently in games?

Heuristics

The background is a solid black field. Overlaid on this are numerous thin, light green lines that crisscross the frame in various directions, creating a complex web-like pattern. At several points where these lines intersect or terminate, there are small, bright green circular dots. Some of these dots have a soft, out-of-focus glow around them, while others are sharper. The overall effect is reminiscent of a digital network, a neural network diagram, or perhaps a stylized representation of a celestial map or molecular structure.

CONTENT ADAPTIVE SHADING

Deriving the error in 1D (X or Y)

CONTENT ADAPTIVE SHADING

Estimate the error per tile

$$\mathcal{E}(\mathbf{I}, \mathbf{I}^H) = \|\mathbf{I} - \mathbf{I}^H\|_2 \cong \sqrt{\sum_N (I_i - I_{i-1})^2} = \|\mathbf{I} * \mathbf{D}\|_2 \quad (\mathbf{D} \text{ is the differencing kernel } [-0.5, 0.5])$$

Instead of using $(I_2 - I_1, I_4 - I_3, \dots)$, we involve all pairs $(I_2 - I_1, I_3 - I_2, I_4 - I_3, \dots)$

- Stabilized result when image is shifted by 1 pixel
- More robust estimation when using previous frame instead of true signal

CONTENT ADAPTIVE SHADING

Error estimate for quarter-rate shading

Full-rate shading

Half-rate shading

Quarter-rate shading

$$\mathcal{E}(I, I^H) = \|I - I^H\|_2 \quad \text{(Mean-squared error)}$$

$$\cong \|I * D\|_2 \quad \text{(D: differencing kernel)}$$

$$= \|\mathcal{F}(I) \cdot \mathcal{F}(D)\|_2 \quad \begin{array}{l} \text{(Convolution and Parseval theorems)} \\ \text{(omitting const. } 1/\sqrt{N}) \end{array}$$

$$= \|\mathcal{F}(I) \cdot (1 - \mathcal{F}(B_2))\|_2 \quad (B_2: \text{box kernel } \tfrac{1}{2}[1,1])$$

$$\mathcal{E}(I, I^Q) = \|\mathcal{F}(I) \cdot (1 - \mathcal{F}(B_4))\|_2 \quad (B_4: \text{box kernel } \tfrac{1}{4}[1,1,1,1])$$

$$= \|\mathcal{F}(I) \cdot (1 - \mathcal{F}(B_2)) \cdot \mathcal{K}\|_2 \quad (K: \text{frequency bin scaling})$$

$$\cong k \cdot \|\mathcal{F}(I) \cdot (1 - \mathcal{F}(B_2))\|_2 \quad \text{(Pre-integration)}$$

$$= k \cdot \|I * D\|_2$$

CONTENT ADAPTIVE SHADING

Determine shading rate

$$\mathcal{E}(I, I^H) \cong \|I * D\|_2$$

Independent decision for X and Y:

$$\mathcal{E}(I, I^H) < \text{threshold} ?$$

Enable half-rate shading

$$\mathcal{E}(I, I^Q) = k \cdot \mathcal{E}(I, I^H) < \text{threshold} ?$$

Enable quarter-rate shading

Use a “Just Noticeable Difference” (JND) threshold (Weber-Fechner Law)

WEBER-FECHNER LAW

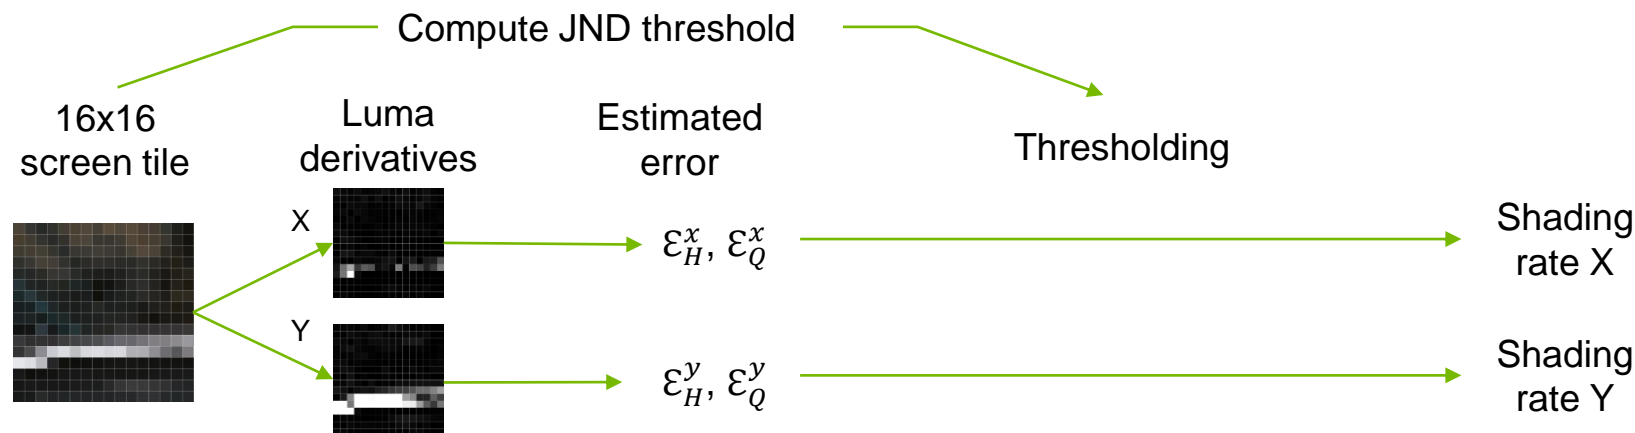

“The just-noticeable difference between two stimuli is proportional to the magnitude of the stimuli”

$$\text{JND_THRESHOLD} = \text{SENSITIVITY_THRESHOLD} * \text{BASE_LUMINANCE}$$

CONTENT ADAPTIVE SHADING

MOTION BLUR AND PERCEIVED ERROR

How motion blur hides VRS error

MOTION ADAPTIVE SHADING

Factor motion influence into adaptive shading

MOTION ADAPTIVE SHADING

Motion-based VRS error estimate scaler

Two scalar functions:

For half-rate: $\epsilon_H(v) = b_H(v) \cdot \epsilon_H$

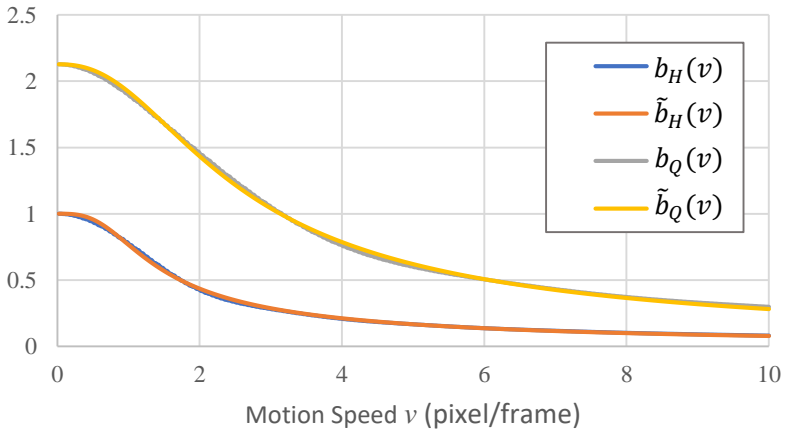

For quarter-rate: $\epsilon_Q(v) = b_Q(v) \cdot \epsilon_H$

We compute $b_H(v)$ and $b_Q(v)$ numerically

Then fit two closed-form functions:

$$\tilde{b}_H(v) = \left(\frac{1}{1 + (1.05v)^{3.10}} \right)^{0.35},$$
$$\tilde{b}_Q(v) = 2.13 \left(\frac{1}{1 + (0.55v)^{2.41}} \right)^{0.49}.$$

(Details in the paper)

ADAPTIVE SHADING PERFORMANCE

Overall cost and benefit

Engine change: add a few compute passes to generate shading rate image

- Simple API calls to enable VRS on forward shading passes
- Overhead: 0.2ms for 4K (2160p) on a RTX2080Ti, completely hidden in async compute

Performance benefit (UE4/id Tech 6) :

- 2x average, up to 5x performance gain in PS-bound forward passes
- 5% - 20% reduction in frame time (~1-3ms saving for 60FPS target)

WOLFENSTEIN II DEMO

50 + 0

SUMMARY

Adaptive shading: now and future

- Use the new GPU feature: VRS - **Minor change in engine, supported by all major APIs**
- Model the shading error with frequency space analysis - **say goodbye to old heuristics**
- 2x average, up to 5x performance gain in forward shading passes
- Visually indistinguishable from full-rate shading

Future work: adaptive shading in non-forward shading passes

- Deferred & post-processing passes using compute pipeline
- Ray tracing
